

SWARM

Updated Business Model · Swarm Economics · Deployment Logic

01 · Updated Strategic Direction

SWARM no longer starts from government deployment.

Initial deployment strategy:

- private territories
- resorts
- vineyards
- agricultural land
- isolated luxury properties

Government integration becomes a later expansion layer.

02 · Correct Wildfire Positioning

SWARM does not initially position itself as autonomous firefighting.

The first deployment layer is:

- wildfire early detection
- anomaly verification
- environmental monitoring
- autonomous response coordination

Long-term expansion: micro-response and suppression capabilities.

03 · Swarm Philosophy

The advantage is not one expensive drone.

The advantage is many cheap autonomous units coordinated together.

The moat becomes:

- orchestration
- mission allocation
- telemetry
- distributed intelligence
- redundancy

04 · Realistic Initial Architecture

Initial deployment:

- 2–6 low-cost autonomous units
- dock/base station
- static sensing layer
- telemetry node
- AI coordination layer

Drones stay docked until anomaly triggers occur.

05 · Example Economics

Example lean deployment:

- 3 micro-units
- basic dock
- environmental sensors
- local compute node

Estimated deployment: €5k–15k.

Possible model:

- setup fee
- recurring subscription

06 · Why Customers Would Pay

Customers are not paying for drones.

Customers are paying for:

- reduced response time
- risk reduction
- territorial awareness
- peace of mind
- continuous monitoring

The value proposition: SWARM reduces the time between ignition and response.

07 · Biggest Insight

The network itself becomes the product.

Hardware gradually commoditizes.

The value shifts toward:

- coordination infrastructure
- environmental intelligence
- operational data
- autonomous orchestration

Many units. One intention.
